identification and recovery of a variety of valuable hydrocarbon-bearing substances from subterranean reservoirs have occurred during the past decade. Because these valuable hydrocarbons are, for the most part, trapped within a subterranean formation, the recovery of the hydrocarbon is usually effected by the in situ production of the hydrocarbon through an injection well penetrating the subterranean formation and a recovery well penetrating the subterranean formation. The recovery well is spaced away from the injection well to provide a

communication path between the injection and recovery wells. The production of the hydrocarbon from the formation to the recovery well is typically effected by a mobile fluid which is injected into the formation through the injection well. The production of the mobile fluid to the recovery well is normally effected by the injection of the mobile fluid through the injection well. The injection of the mobile fluid into the formation is normally effected by an injection well located above the recovery well. The communication path between the injection and

recovery wells may be open during the injection of the mobile fluid into the formation or may be temporarily opened and then closed at the end of the injection. For example, in the case of a large gas injection well, the communication path may be open between the injection and recovery wells for the first half of the injection period and then closed during the second half of the injection period. In a typical situation, the injection well is closed off from the recovery well by placing a plug in the injection well near the end of the injection period to block the injection well from the

recovery well. The injection well, if it contains a packer and produces the hydrocarbon, may be a mature well having the injection well spaced from the production well 2d92ce491b
