Topography of functionalized polymer/DNA nanocomposites. Using single-stranded DNA, neutral and cationic polymers are successfully prepared and characterized. These materials are used to prepare Langmuir monolayers at the air-water interface. These films were analysed by X-ray diffraction, infrared spectroscopy and atomic force microscopy. We demonstrate that the Langmuir film composed of poly(ethylene imine) and oligo-DNA is able to release entrapped proteins from bacteria cells. This release is a reversible process and can be controlled by the ionic strength of the buffer.

---

is a need to include biological knowledge of how different types of microbes interact with other living organisms, the environment and each other in order to construct model-based quantitative frameworks that include environmental heterogeneity and topology. The research reported in this publication was supported by the National Science Foundation (\#NSF-EF-0322567 and \#NSF-EF-0828334), the U.S. Environmental Protection Agency (EPA) (\#R826784 and \#RD834891), and the U.S. Geological Survey (USGS) (\#RC-5440-5, \#RC-5440-9). Any opinions, findings, and conclusions or recommendations expressed in this material are those of the author(s) and do not necessarily reflect the views of the NSF, the EPA, the USGS, or any other institution with which any of the authors are affiliated.
