Welcome to the best place to buy the liang gie pengantar filsafat ilmu pdf. These titles represent the good quality of the input texts, which is very important for the classifier training. The compromise between precision and recall depends on the number of the positive and negative sample items in the training data set. In the following text, we demonstrate how to build a document-level classifier (classification task) based on various character-level language representations by employing the proposed methodology.

Image by Neel Mukherjee

How to build a document-level classifier is the topic of this post. Consider for example an email corpus, or a document collection, where we want to build a binary classification rule that predicts whether a document or e-mail is spam. We have a set of 20000 training text documents, and an equally large set of validation text documents. Based on these two sets, we build a classifier. In other words, the baseline is represented by an SVM classifier. We use a linear SVM, with five values for the regularization parameter  $C$ . Each text document is represented as a vector of size 20. This vector contains the word frequencies for the 20 most common words. The classifier is trained on the training set, and then tested on the validation set. The output of the classifier is a label. In this example, we choose whether or not the document is spam. Finally, we report two important metrics: Precision and Recall (Figure 1). The red point represents the resulting precision and recall after classifier training. The precision refers to the proportion of correct classifications. We see that the precision of the classifier is low, i.e. it misclassifies many documents. This is due to the fact that the classifier is trained on a very large number of text documents, but has to make a binary decision about whether a document is spam or not. If the number of training documents is smaller (say, if we trained the classifier on data from one single spam site instead of on 20000 training documents), then the precision of the classifier is significantly higher. However, it is not surprising that a classifier trained on a large set of documents is more prone to make mistakes.
