Switch encoding format between UTF-8 and ANSI (and vice versa); Convert Unicode text to ANSI; Convert ANSI text to Unicode; Apply or remove UTF-8 prefix; Auto-convert all UTF-8 plain text files; Remove ASCII character set prefixes. For more details, go to the official website of UTF8 Tool. A: If you are converting text files, then this is probably what you want. From The Internet (where I got the following from) Kai Schär, his website, the Informationspage at the site of the German Type Committee - The W3C Reference is a very concise description of the Unicode Standard and the UTF8 Character Encoding, which I will not copy here since I

am too lazy for that. In UTF-8, each character can be represented with only one byte, however, this byte can take on many different values. This is a problem that can be solved by using additional 8-bit bytes, allowing the characters to be represented by up to 4 bytes at the same time. UTF-8 is one of the newer Unicode encodings. It was officially standardized by the Unicode Consortium and is very widely used. Because UTF-8 uses only one byte per character, it is easier to handle than the Unicode (exact) encoding which uses several bytes per character. However, it has the disadvantage that the encoding is well suited for the representation of characters in the ASCII character set but not for well-known Asian languages. Most of the characters in the world are already in UTF-8 form, either internally in computer text documents or in

other media. Simply browsing the Internet or reading text files often converts the characters to the UTF-8 format, e.g. when you read documents on the Web, the encoded characters are loaded into the cache of your browser. When you have downloaded any HTML document, you get the source-code of the document, which is in UTF-8. In the following document you will find an extensive list of all the characters in Unicode that can be represented in UTF-8. A: The file I eventually chose is this one:

GRID The difference is that while `utf8_to_ansi` also converts plain text between UTF-8 and ANSI codes, Grid encodes to and decodes from Unicode. An encoding is a generic term for all the ways computers store the text in the same way, while a decoding is the reverse process. The Unicode standard is the result of years of intense work by many different people and it is a fairly complicated piece of work. In addition to the Latin alphabet, Unicode contains symbols for the following languages: Arabic,

Armenian, Bengali, Bopomofo, Brahmi, Bulgarian, Burmese, Chinese, Czech, Danish, Dutch, Estonian, Finnish, French, Galician, Georgian, German, Greek, Gujarati, Hebrew, Hindi, Hungarian, Icelandic, Indonesian, Irish, Japanese, Kazakh, Khmer, Korean, Kannada, Korean, Macedonian, Malay, Malaysian, Maltese, Mongolian, Norwegian, Persian, Polish, Portuguese, Romanian, Russian, Serbian, Slovak, Slovene, Spanish, Sundanese, Swahili, Swati, Swedish, Tahitian, Tamil, Telugu, Thai, Tibetan, Turkish, Turkmen, Ukrainian, Urdu, Vietnamese, Welsh and Yiddish. A: You are looking for the `unicode-utils` package: Then the

`utf8_to_ansi_or_ansi_to_utf8_or_any_other_direction` function will do exactly what you want. Another useful option if you want to do the conversion from UTF-8 to

other encodings is:

Q: How to use parameterized query to update table I want to update a table for each id in the list, so I wrote

this code

```
SqlCommand cmd = new  
SqlCommand("UPDATE Test SET id = @value  
WHERE id = @id", con);  
cmd.Parameters.AddWithValue("@value", dr["id"]);  
cmd.Parameters.AddWithValue("@id", dr["id"]);
```

but I get an error An unhandled exception of type 'System.InvalidOperationException' occurred in System.Data.dll Additional information: Invalid attempt to read when no data is present.

dr["id"] = 1;
dr["id"] = 2; dr["id"] = 3; dr["id"] = 4;

A: UPD: one of the problems is that I used an sql statement with select instead of update

- (1) That SQL statement with select is correct. At least you should understand what it does.
- (2) Since you use a parameterized query: using (var connection = new SqlConnection(connectionString)) { using (var command = new SqlCommand("SELECT

```
@value as 'Id1"', connection)) {  
    command.Parameters.AddWithValue("@value", "a");  
    using (var command2 = new SqlCommand("UPDATE  
        Test SET Id = @value", connection)) {
```
