A file system is a type of data storage on a computer. All modern file systems are generally based on a file system architecture, which uses a collection of data structures known as a file system. The first file systems were for MS-DOS, but the form has evolved into the widely used hierarchical filesystem, introduced to Apple computers with the "Macintosh File System" and commonly found on Unix systems as well as in workstation and server-class Windows systems. File systems are similar to the database management systems in the fact that they are used for organizing computer data. However, a file system is usually used to store computer data in addition to the data in the application programs, whereas a database management system is mainly used to organize data in other applications. File systems are organized into directories, which are the basis for the file pathname system. All files and directories reside on storage. The file system is responsible for keeping track of the location of individual files and for making them accessible to the application programs when needed. Windows file systems Browsing through the Windows filesystem can be done using the Windows Explorer program, or the Windows command shell. It is possible to change the way directories and files are arranged, and to rename and remove directories and files. The first file systems and the earliest operating system for personal computers were MS-DOS-based, relying on the MS-DOS file management system. Microsoft introduced a new, proprietary file system with Windows 3.1 in 1994, and added a simple file manager called the Windows Explorer to Windows 95 in 1995 b7e8fd5c8
